Description

Various utilities for the complex multivariate Gaussian distribution and complex Gaussian processes.

Details

The DESCRIPTION file:

Package:	cmvnorm
Type:	Package
Title:	The Complex Multivariate Gaussian Distribution
Version:	1.0-7
Authors@R:	person(given=c("Robin", "K. S."), family="Hankin", role = c("aut", "cre"), email="hankin.robin@gmail.com")
Depends:	emulator (>= 1.2-21)
Suggests:	knitr
Imports:	elliptic
Maintainer:	Robin K. S. Hankin <hankin.robin@gmail.com>
Description:	Various utilities for the complex multivariate Gaussian distribution and complex Gaussian processes.
VignetteBuilder:	knitr
License:	GPL-2
URL:	https://github.com/RobinHankin/cmvnorm
BugReports:	https://github.com/RobinHankin/cmvnorm/issues
Author:	Robin K. S. Hankin [aut, cre] (< https://orcid.org/0000-0001-5982-0415 >)

Index of help topics:

Im<-	Manipulate real or imaginary components of an object
Mvcnorm	Multivariate complex Gaussian density and random deviates
cmvnorm-package	The Complex Multivariate Gaussian Distribution
corr_complex	Complex Gaussian processes
isHermitian	Is a Matrix Hermitian?
var	Variance and standard deviation of complex vectors
wishart	The complex Wishart distribution

Generalizing the real multivariate Gaussian distribution to the complex case is not straightforward but one common approach is to replace the real symmetric variance matrix with a Hermitian positive-definite matrix. The **cmvnorm** package provides some functionality for the resulting density function.

Examples

```
S1 <- 4+diag(5)
S2 <- S1
S2[1,5] <- 4+1i
S2[5,1] <- 4-1i    # Hermitian

rcmvnrm(10,sigma=S1)
rcmvnrm(10,mean=rep(1i,5),sigma=S2)

dcmvnrm(rep(1,5),sigma=S2)
```

corr_complex

*Complex Gaussian processes***Description**

Various utilities for investigating complex Gaussian processes

Usage

```
corr_complex(z1, z2 = NULL, distance.function = complex_CF, means =
NULL, scales = NULL, pos.def.matrix = NULL)
complex_CF(z1,z2, means, pos.def.matrix)
scales.likelihood.complex(pos.def.matrix, scales, means, zold, z,
give_log = TRUE, func = regressor.basis)
interpolant.quick.complex(x, d, zold, Ainv, scales = NULL, pos.def.matrix = NULL,
means=NULL, func = regressor.basis, give.Z = FALSE,
distance.function = corr_complex, ...)
```

Arguments

<code>z, z1, z2</code>	Points in C^n
<code>distance.function</code>	Function giving the (complex) covariance between two points in C^n
<code>means, pos.def.matrix, scales</code>	In function <code>complex_CF()</code> , the mean and covariance matrix of the distribution whose characteristic function is used to give the covariance matrix; <code>scales</code> is used to specify the diagonal of <code>pos.def.matrix</code> if the off-diagonal elements are zero
<code>zold, d, give_log, func, x, Ainv, give.Z, ...</code>	Direct analogues of the arguments in <code>interpolant()</code> and <code>scales.likelihood()</code> in the emulator package

Details

- Function `complex_CF()` returns a (slightly reparameterized) characteristic function of a complex Gaussian distribution. The covariance is given by

$$c(\mathbf{t}) = \exp(i\text{Re}(\mathbf{t}^* \boldsymbol{\mu}) - \mathbf{t}^* B \mathbf{t})$$

where $\mathbf{t} = \mathbf{x} - \mathbf{x}'$ is interpreted as the distance between two observations, $\boldsymbol{\mu}$ is the mean of the distribution (which is in general a complex vector), and B a positive-definite matrix.

- Function `corr_complex()` is the complex analogue of `corr.matrix()`. It returns a matrix with entry (i, j) equal to the covariance of the process at observation i and observation j , or $\text{cov}(\eta(\mathbf{x}_i), \eta(\mathbf{x}_j))$. The elements are calculated by `complex_CF()`. This function includes only a single method, that of nested calls to `apply()`. I could not figure out how to generalize method 1 of `corr.matrix()` to the complex case.
- Function `scales.likelihood.complex()` is a complex version of `scales.likelihood()` which takes a positive definite matrix and a mean. The formula used is

$$(\sigma^2)^{-(n-q)} |A|^{-1} |H^* A^{-1} H|^{-1}$$

. Here and elsewhere, A^* means the complex conjugate of the transpose.

- Function `interpolant.quick.complex()` is a complex version of `interpolant.quick()`.

$$\mathbf{h}(\mathbf{x})^* \hat{\beta} + \mathbf{t}(\mathbf{x})^* A^{-1} (\mathbf{y} - H \hat{\beta})$$

This is the complex version of Oakley's equation 2.30 or Hankin's equation 5.

More details are given in the package vignette.

Examples

```

complex_CF(c(1,1i),c(1,-1i),means=c(1i,1i),pos.def.matrix=diag(2))

V <- latin.hypercube(7,2,complex=TRUE)

cm <- c(1,1+1i)           # "complex mean"
cs <- matrix(c(2,1i,-1i,1),2,2)  # "complex scales"
tb <- c(1,1i,1-1i)         # "true beta"

A <- corr_complex(V,means=cm,pos.def.matrix=cs)
Ainv <- solve(A)
z <- drop(rmvnorm(n=1,mean=regressor.multi(V) %*% tb, sigma=A))

betahat.fun(V,Ainv,z)    # should be close to 'tb'

#scales.likelihood.complex(cs,cm,V,z)  # log-likelihood evaluated true parameters

interpolant.quick.complex(x=0.1i+V[1:3,],d=z,zold=V,Ainv=Ainv,pos.def.matrix=cs,means=cm)

```

isHermitian

Is a Matrix Hermitian?

Description

Returns TRUE if a matrix is Hermitian or Hermitian positive-definite

Usage

```

isHermitian(x, tol = 100 * .Machine$double.eps)
ishpd(x,tol= 100 * .Machine$double.eps)
zapim(x,tol= 100 * .Machine$double.eps)

```

Arguments

x	A square matrix
tol	Tolerance for numerical scruff

Details

Functions `isHermitian()` and `ishpd()` return a Boolean, indicating whether the argument is Hermitian or Hermitian positive definite respectively. Function `zapim()` zaps small imaginary parts of a vector, returning real if all elements are so zapped.

Author(s)

Robin K. S. Hankin

Examples

```
v <- 2^(1:30)
zapim(v+1i*exp(-v))

ishpd(matrix(c(1,0.1i,-0.1i,1),2,2)) # should be TRUE
isHermitian(matrix(c(1,3i,-3i,1),2,2)) # should be TRUE
ishpd(rcwis(6,2)) # should be TRUE
```

Mvcnrm

Multivariate complex Gaussian density and random deviates

Description

Density function and a random number generator for the multivariate complex Gaussian distribution.

Usage

```
rcnorm(n)
dcmvnorm(z, mean, sigma, log = FALSE)
rcmvnorm(n, mean = rep(0, nrow(sigma)), sigma = diag(length(mean)),
method = c("svd", "eigen", "chol"),
tol= 100 * .Machine$double.eps)
```

Arguments

z	Complex vector or matrix of quantiles. If a matrix, each row is taken to be a quantile
n	Number of observations
mean	Mean vector
sigma	Covariance matrix, Hermitian positive-definite
tol	numerical tolerance term for verifying positive definiteness
log	In <code>dcmvnorm()</code> , Boolean with default FALSE meaning to return the Gaussian density function, and TRUE meaning to return the logarithm
method	Specifies the decomposition used to determine the positive-definite matrix square root of <code>sigma</code> . Possible methods are eigenvalue decomposition ("eigen", default), and singular value decomposition ("svd")

Details

Function `dcmvnorm()` is the density function of the complex multivariate normal (Gaussian) distribution:

$$p(\mathbf{z}) = \frac{\exp(-\mathbf{z}^*\Gamma\mathbf{z})}{|\pi\Gamma|}$$

Function `rnorm()` is a low-level function designed to generate observations drawn from a standard complex Gaussian. Function `rcmvn()` is a user-friendly wrapper for this.

Author(s)

Robin K. S. Hankin

References

N. R. Goodman 1963. “Statistical analysis based on a certain multivariate complex Gaussian distribution”. *The Annals of Mathematical Statistics*. 34(1): 152–177

Examples

```
S <- emulator::cprod(rcmvn(3,mean=c(1,1i),sigma=diag(2)))

rcmvn(10,sigma=S)
rcmvn(10,mean=c(0,1+10i),sigma=S)

# Now try and estimate the mean (viz 1,1i) and variance (S) from a
# random sample:

n <- 101
z <- rcmvn(n,mean=c(0,1+10i),sigma=S)
xbar <- colMeans(z)
Sbar <- cprod(sweep(z,2,xbar))/n
```

Description

Manipulate real or imaginary components of an object

Usage

```
Im(x) <- value
Re(x) <- value
```

Arguments

<i>x</i>	Complex-valued object
<i>value</i>	Real-valued object

Author(s)

Robin K. S. Hankin

Examples

```
A <- matrix(c(1,0.1i,-0.1i,1),2,2)
Im(A) <- Im(A)*3
Re(A) <- matrix(c(5,2,2,5),2,2)
```

var

Variance and standard deviation of complex vectors

Description

Complex generalizations of `stats::sd()` and `stats::var()`

Usage

```
var(x, y=NULL, na.rm=FALSE, use)
sd(x, na.rm=FALSE)
```

Arguments

<i>x, y</i>	Complex vector or matrix
<i>na.rm</i>	Boolean with default FALSE meaning to leave NA values present and TRUE meaning to remove them
<i>use</i>	Ignored

Details

Intended to be broadly compatible with `stats::sd()` and `stats::var()`.

If given real values, `var()` and `sd()` return the variance and standard deviation as per ordinary real analysis. If given complex values, returns the complex generalization in which Hermitian transposes are used.

If `z` is a complex matrix, `var(z)` returns the variance of the rows.

These functions use $n - 1$ on the denominator purely for consistency with `stats::var()` (for the record, I disagree with the rationale for $n - 1$).

Author(s)

Robin K. S. Hankin

Examples

```
sd(rchnorm(10)) # imaginary component suppressed by zapim()

var(rcmvnorm(1e5,mean=c(0,0)))
```

wishart

The complex Wishart distribution

Description

Returns an observation drawn from the complex Wishart distribution. To sample from the inverse complex Wishart distribution (or indeed the complex inverse Wishart distribution), use `solve(rcwis(...))`.

Usage

```
rcwis(n, S)
```

Arguments

<code>n</code>	Integer; degrees of freedom
<code>S</code>	Variance matrix. If an integer, use <code>diag(nrow=S)</code>

Value

Returns a (semi-) positive definite Hermitian matrix the same size as argument `S`

Note

The first argument of `rcwis()` is `n`, by universal statistics convention. But in the R world, functions returning random observations (such as `rnorm()`) generally reserve argument `n` for the number of observations to return. Although `rchiq()` uses `df` for the number of degrees of freedom.

Author(s)

Robin K. S. Hankin

Examples

```
rcwis(10,2)
eigen(rcwis(7,3),TRUE,TRUE)    # all positive
eigen(rcwis(3,7),TRUE,TRUE)    # 4 positive, 3 zero

rcwis(10,rcwis(10,3))
```
